🌊 Cascading in CSS

Cascading = the process CSS uses to decide **which rule applies when multiple rules target the same element**.

🧠 Priority Order (top wins):

1. **Importance**
    a. `!important` 🚨 (nuclear override)
2. **Specificity**
3. **Source order (last rule wins)**

🧪 Example:

```
p {
    color: blue;
}

p {
    color: red;
}
```

👉 Output: **red**
Because the *last rule wins* (same specificity)

⚠️ With `!important`

```
p {
    color: blue !important;
}

p {
    color: red;
}
```

👉 Output: **blue** (even though it's earlier 😈)

🎯 Specificity in CSS

Specificity is like a scoring system 🧮 that decides which selector is stronger.

🧮 Specificity Score Format

`Inline > ID > Class > Element`

Or numerically:

Selector Type	Score
Inline style	1000
ID (`#id`)	100
Class (`.class`) / pseudo-class	10
Element (p, h1) / pseudo-element	1
