💧 flex-basis kya hota hai

👉 **Item ki starting size (initial size) kya hogi before grow/shrink**

- matlab: item **shuru me kitni jagah lega**
- uske baad hi `flex-grow` aur `flex-shrink` ka game start hota hai

🧠 Ek line yaad rakh

👉 **flex-basis = "starting size before adjustment"**

🎯 Example (seedha samajh)

```
.item {
  flex-basis: 200px;
}
```

👉 har item pehle **200px lega**
👉 phir:

- extra space → grow hoga
- kam space → shrink hoga

⚡ Important twist (ye hi confusion hota hai)

👉 `flex-basis` ≠ final size

👉 ye sirf **starting point hai**

Final size depend karega:

- grow

- shrink
- container size

🎮 Full flow samajh (ultimate clarity)

Flexbox 3 steps me kaam karta hai:

1. **Step 1:** sab items apni `flex-basis` size lete hain
2. **Step 2:** check hota hai space bacha ya kam hai
3. **Step 3:**
    a. extra → `flex-grow`
    b. kam → `flex-shrink`

🎯 Example (real combo 🚀)

```
.item {
  flex-basis: 100px;
  flex-grow: 1;
}
```

👉 sab items start = 100px

👉 extra space = evenly divide

🎯 Another powerful case

```
.item {
  flex-basis: 0;
  flex-grow: 1;
}
```

👉 start size = 0 😳

👉 pura space = equally divide

🔥 this is how people make equal columns

⚠️ Default value

```
flex-basis: auto;
```

👉 matlab:

- content ke according size lega
- ya width/height ke according
