🧠 Real definition (the powerful version)

`flex-grow` decides **how much of the remaining space each item gets, based on ratio**

🎯 Case 1: All items same

```
.item {
  flex-grow: 1;
}
```

Imagine:

- Container = 500px
- Items total = 300px
- Remaining space = 200px

👉 4 items → each gets **200 / 4 = 50px**

✔️ YES, evenly divided

🎯 Case 2: Different values (this is where magic happens 🧙‍♂️)

```
.item1 { flex-grow: 1; }
.item2 { flex-grow: 2; }
.item3 { flex-grow: 1; }
```

Now think like this:

- Total grow = 1 + 2 + 1 = **4 parts**
- Remaining space = 200px

👉 Distribution:

- item1 → 1/4 → 50px
- item2 → 2/4 → 100px
- item3 → 1/4 → 50px

✔ Not equal
✔ Based on ratio

⚡ Golden Rule (never forget this)

flex-grow is **not about equal division**
it's about **proportional distribution**

🚫 Important detail most beginners miss

- It only works on **remaining (extra) space**
- If no extra space → `flex-grow` does nothing
